

# Software architecture

---

## Representation

Gabriel Pedraza

[pedraza@imag.fr](mailto:pedraza@imag.fr)

# Outline

---

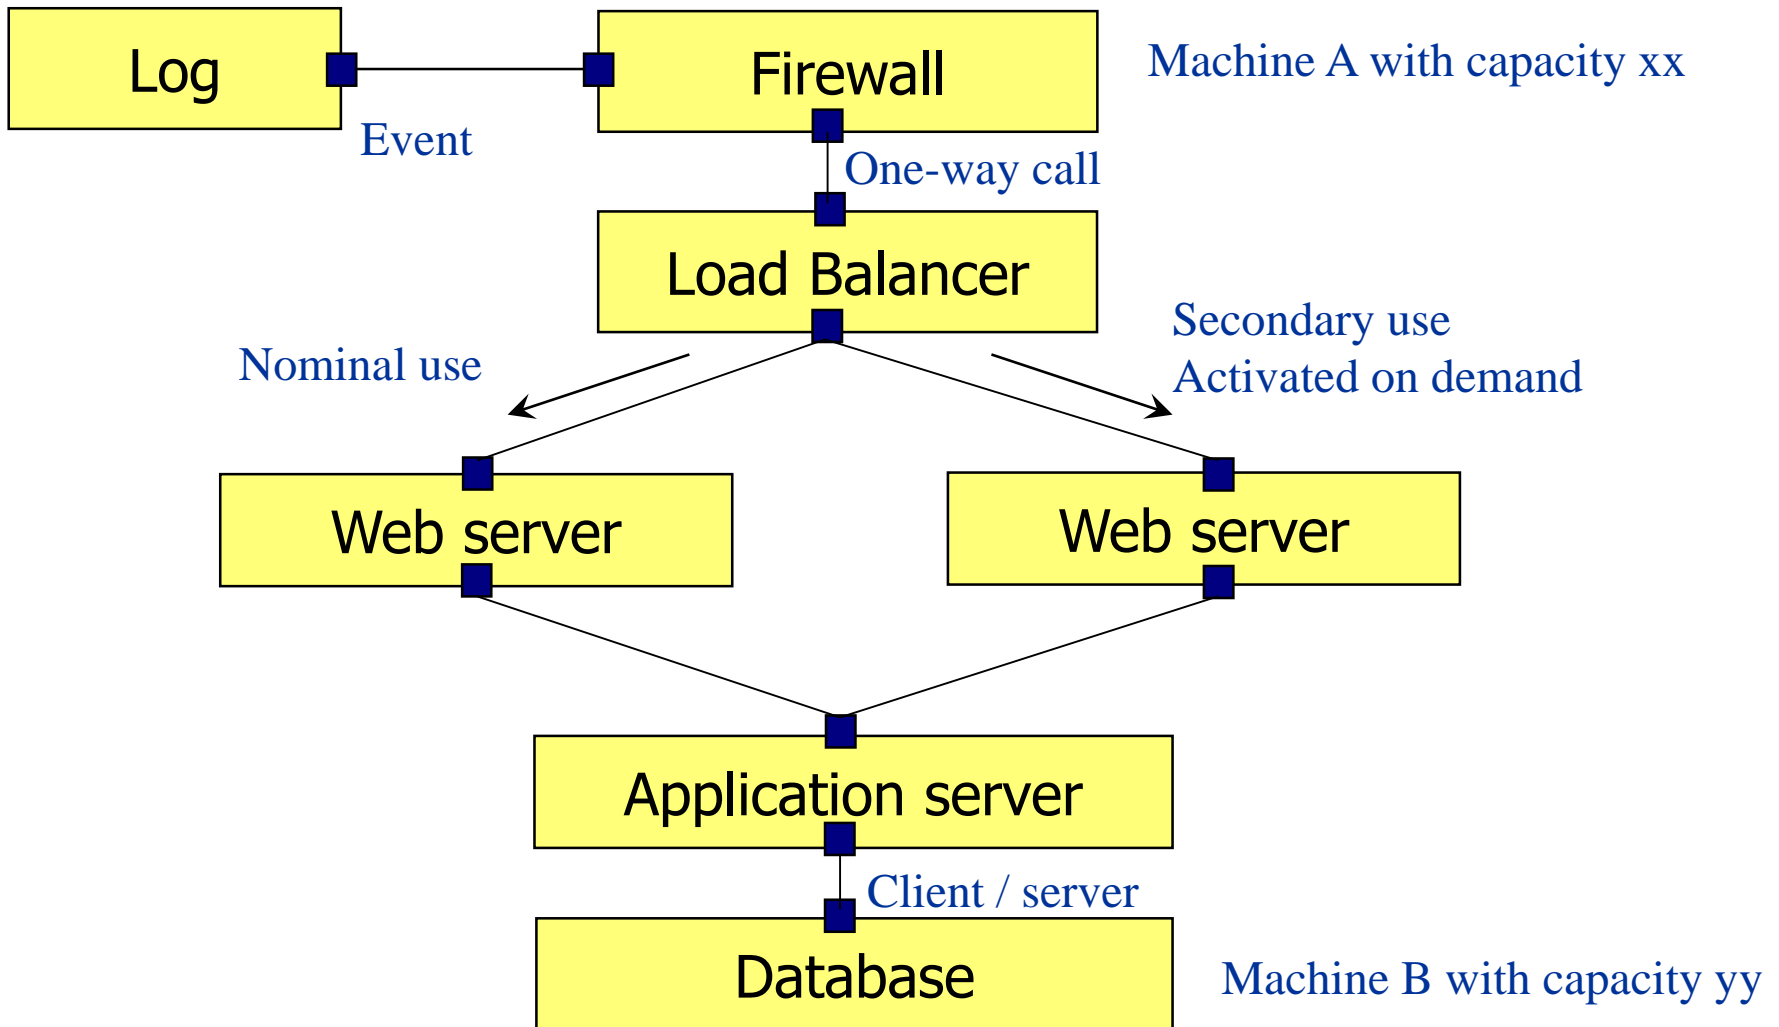

- Architectural views
- Logical views
- Dynamic views
- Allocation views
- Conclusion

# Representing architectures

---

- ❑ The goal is to represent all the information related to software components
  - ❑ Structure and interfaces
  - ❑ Interaction
  - ❑ Properties and constraints
  - ❑ Runtime support, ...
  - ❑ Partnerships
- ❑ Ideally, this information should be represented on a single schema

# Example

# Verdict

---

- ❑ Heterogeneous, incomplete, ambiguous
  - ❑ Very different pieces of information targeting various people
    - ❑ Concerns mixing
    - ❑ Hard to read
  - ❑ Lots of information are missing
    - ❑ How many machines?
    - ❑ Connectors between web servers and application server?
    - ❑ Protocol between firewall and load balancer?
- ❑ Need of structured, repeatable approach

# Analogy

---

- ❑ In buildings, several structures coexist
  - ❑ Topology
  - ❑ Electrical wires
  - ❑ Plumbery
  - ❑ HVAC structures
- ❑ Specialized plans used as specifications
  - ❑ Used by different persons
    - ❑ Maçons, plumbers, ...
  - ❑ Used to specify different properties
    - ❑ Density, diameters, pressure, ...

# Application to software

---

- ❑ Several structures also coexist in software programs (Parnas, 74)
  - ❑ Different programming tools are provided to express these structures
    - ❑ Type definition, loop operators, ...
- ❑ This has to be applied to software architecture

# Application to software

---

- ❑ Several structures also coexist in software programs (Parnas, 74)
  - ❑ Different programming tools are provided to express these structures
    - ❑ Type definition, loop operators, ...
- ❑ This has to be applied to software architecture

# Software views - definition

---

- ❑ A view provides a focused perspective on a software
  - ❑ Separation of concern
- ❑ A view defines
  - ❑ Soft. elements that can be represented on the view
  - ❑ Relations that can be represented
  - ❑ Constraints that can be represented
  - ❑ A formalism and a vocabulary

# Usual views

---

- ❑ Logical views
  - ❑ How the software is structured into components
- ❑ Dynamic views
  - ❑ How the software behaves
- ❑ Allocation views
  - ❑ How the components are executed

# Lost?

---

- ❑ Not having a single view brings good and bad points
  - ❑ Better coherence
  - ❑ Complexity reduction
  - ❑ Focus improvement
  
- ❑ The architecture dematerializes ...
- ❑ Relationships between views ...

# Synthesis

---

Architecture = component + connector

Representation = a set of views

# Outline

---

- ❑ Architectural views
- ❑ Logical views
- ❑ Dynamic views
- ❑ Allocation views
- ❑ Conclusion

# Logical view

---

- ❑ It defines the structure of the architecture
  - ❑ Decomposition into logical elements
- ❑ All components and connectors are described
  - ❑ Connections are potential
  - ❑ Connectors can be complex

# Logical view: components

---

- ❑ A component is defined by
  - ❑ A unique name
  - ❑ Several ports
  - ❑ Properties (performance, persistence, robustness, ...)
- ❑ A port contains
  - ❑ Provided services (functional, lifecycle related, ...)
  - ❑ Required services
  - ❑ Constraints (pre and post, scheduling, ...)

# Logical view: interactions

---

- ❑ Role
  - ❑ Communication
  - ❑ Coordination
  - ❑ Conversion
  - ❑ Facilitation
- ❑ Communication modes
  - ❑ « Procedure Call » (PC, RPC, C/S, methods, ...)
  - ❑ « event » (P/S, broadcast)
  - ❑ « Stream », ...

# Logical view: interest

---

- ❑ Provides answers to the following questions
  - ❑ What are the main computing elements?
  - ❑ What are their relations?
  - ❑ What are the main data sources?
  - ❑ What are the need in terms of supporting runtime?
  - ❑ What are the possible bottlenecks?
  - ❑ What are the critical paths?
  - ❑ What are the levels of coupling and cohesion?

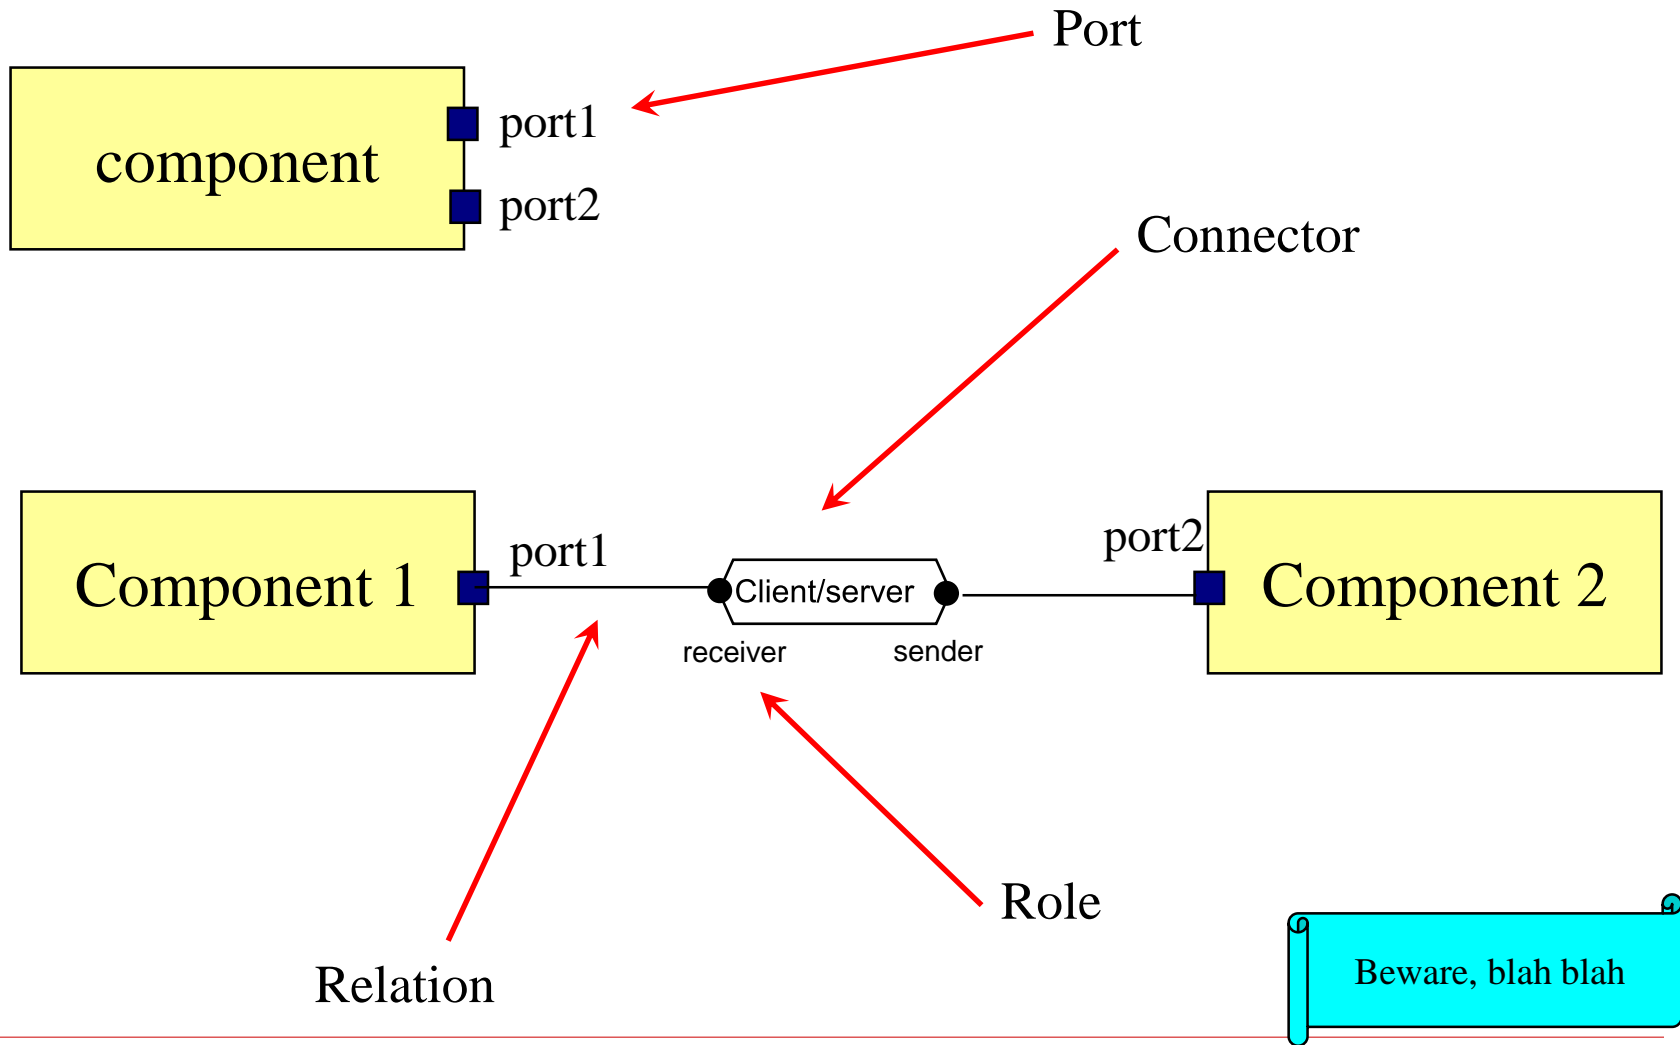

# Logical view: usage example

---

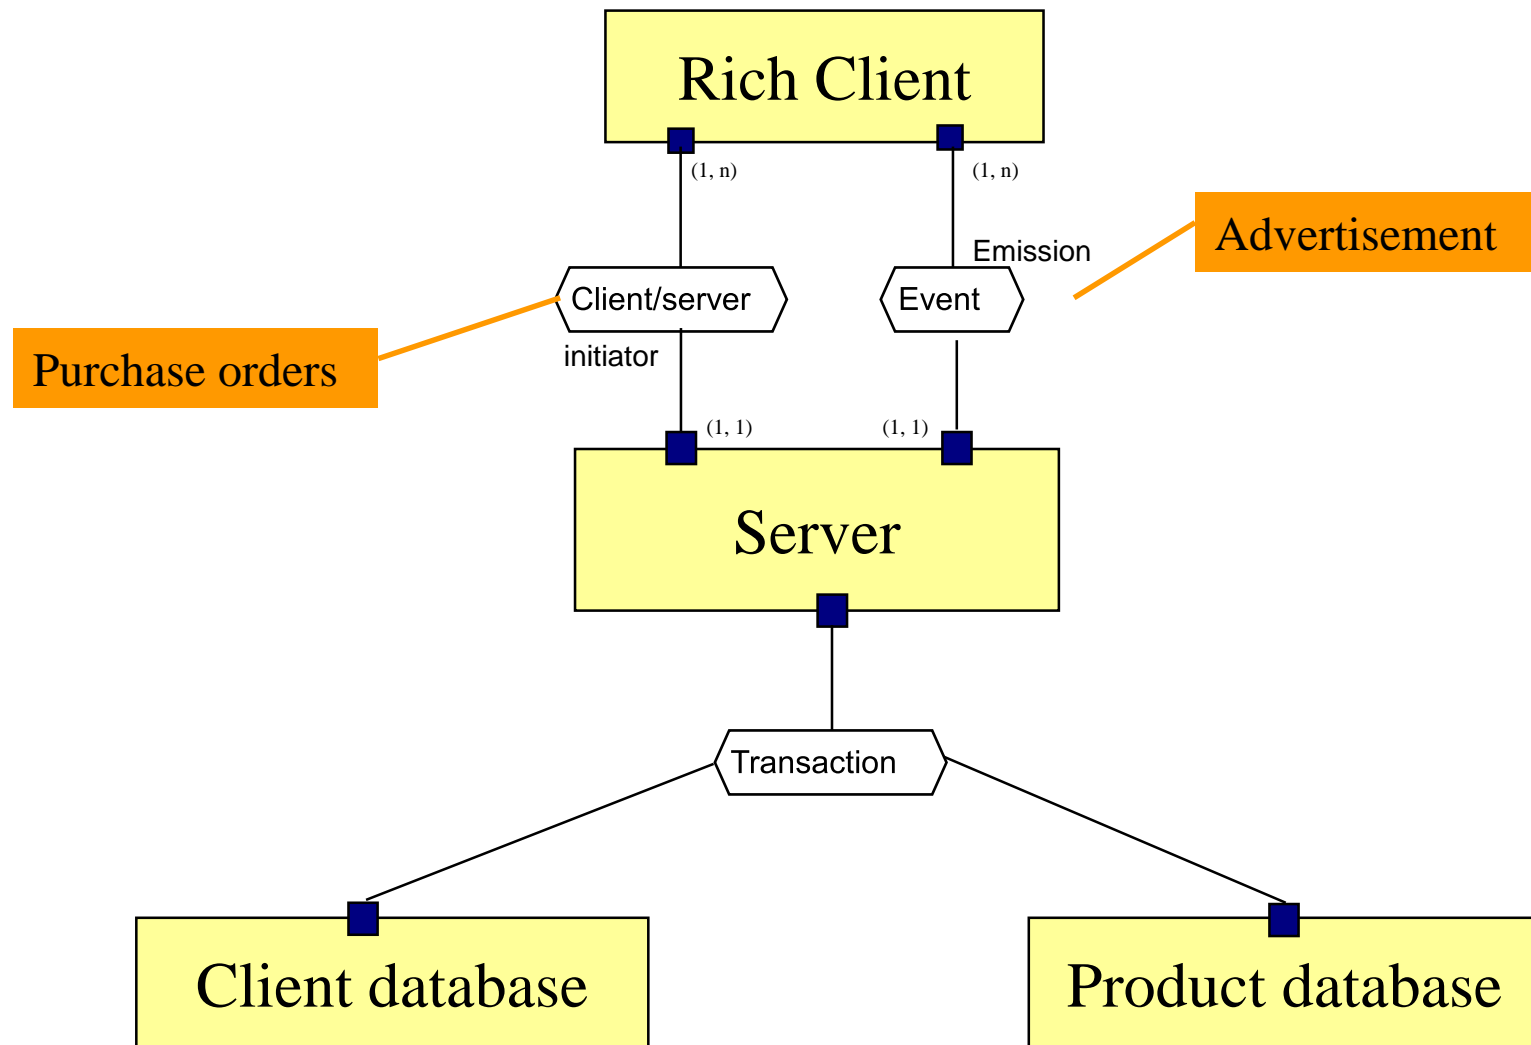

- ❑ Issues
  - ❑ Bottlenecks,
  - ❑ Use of every interface

# Logical view: formalism

# Example: a vending application

# Outline

---

- ❑ Architectural views
- ❑ Logical views
- ❑ **Dynamic views**
- ❑ Allocation views
- ❑ Conclusion

# Dynamic view

---

- ❑ It defines interaction within the architecture
  - ❑ When and why do they occur?
  - ❑ How are they realized?
- ❑ Only effective relations are presented

# Dynamic view: usage example (1)

---

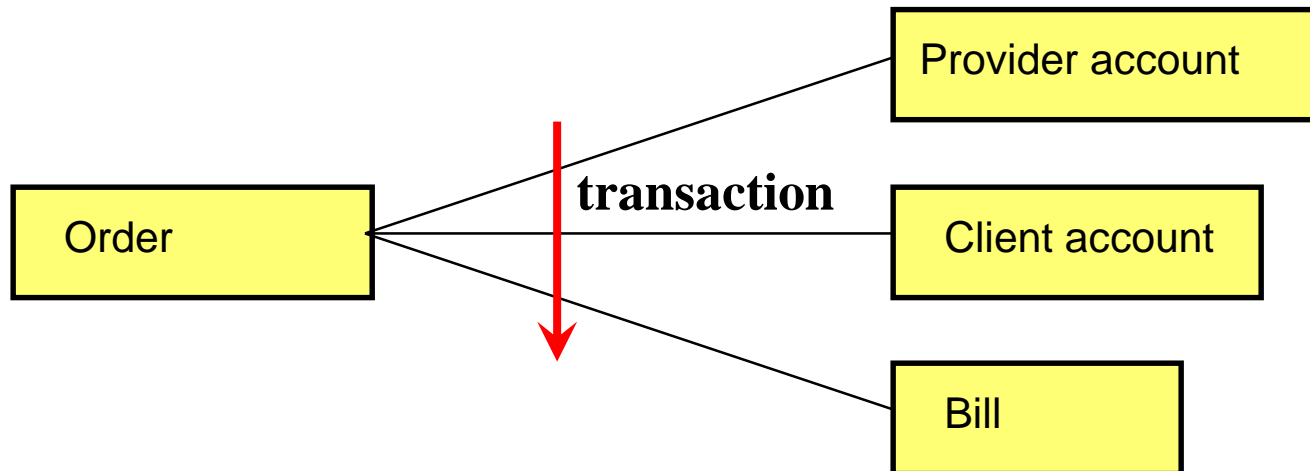

- ❑ Real time systems
  - ❑ Events and durations are specified to ensure performance, reliability

# Dynamic view: usage example (2)

---

- ❑ Banking systems
  - ❑ Transactions are specified to allow rollbacks

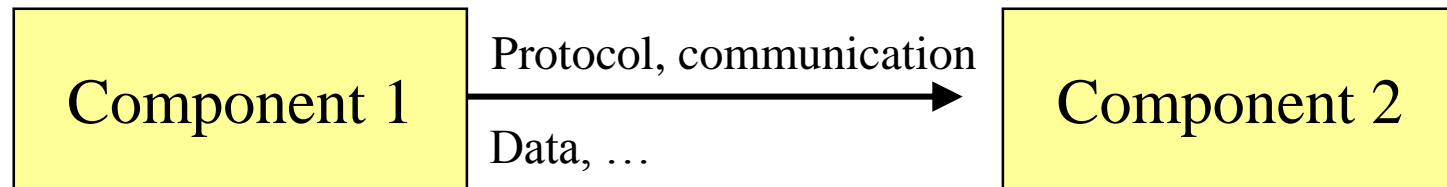

# Dynamic view: interactions

---

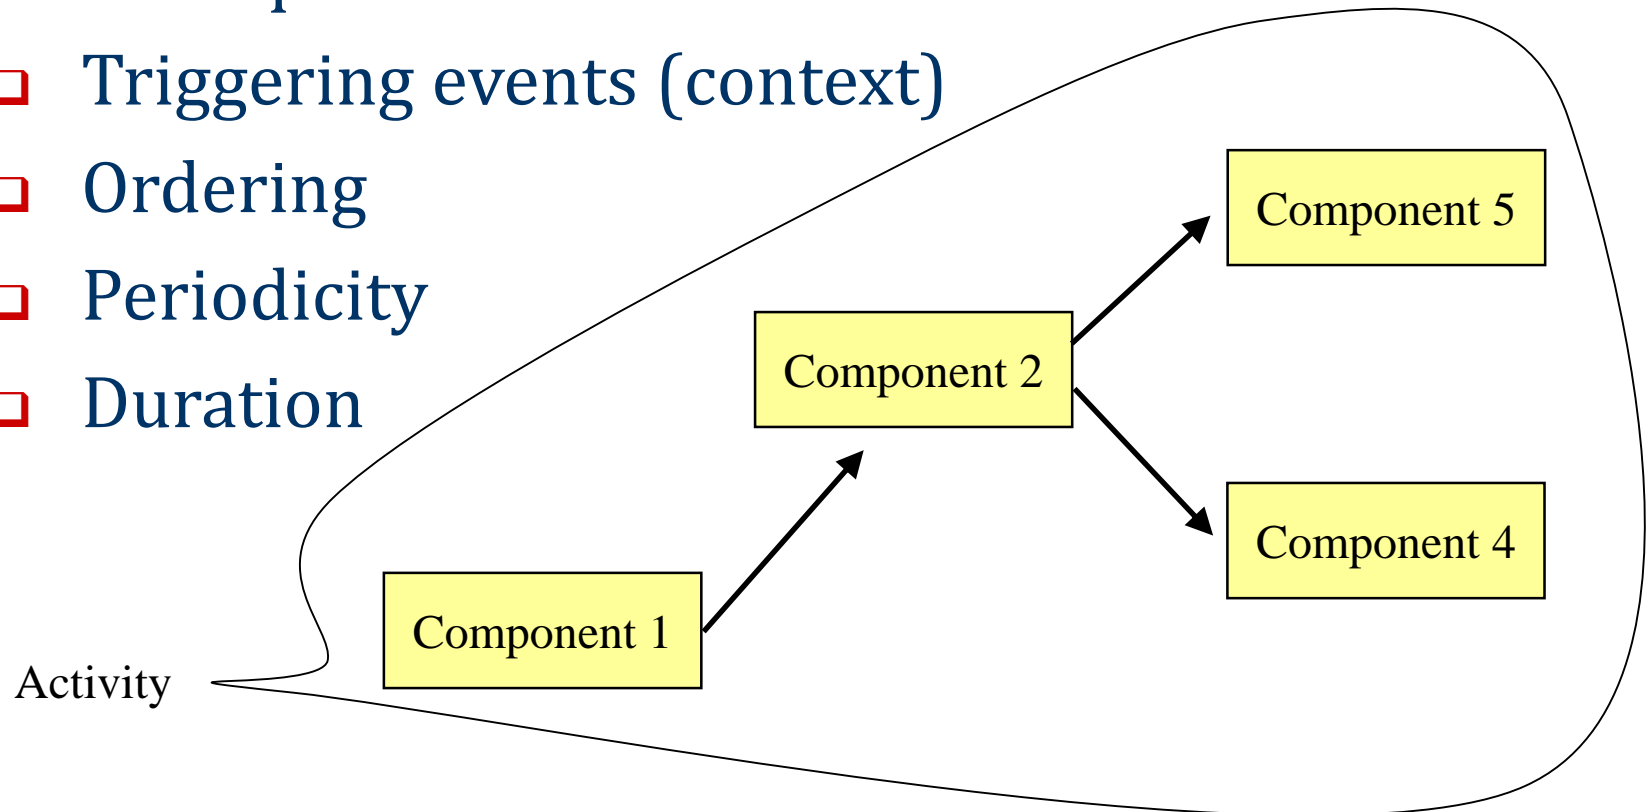

- ❑ An interaction is defined by
  - ❑ Communication type
  - ❑ Exchanged data
  - ❑ Concurrency (possible)

# Dynamic view: activities

---

- ❑ An activity is defined by
  - ❑ A unique name
  - ❑ Triggering events (context)
  - ❑ Ordering
  - ❑ Periodicity
  - ❑ Duration

# Representing dynamics

---

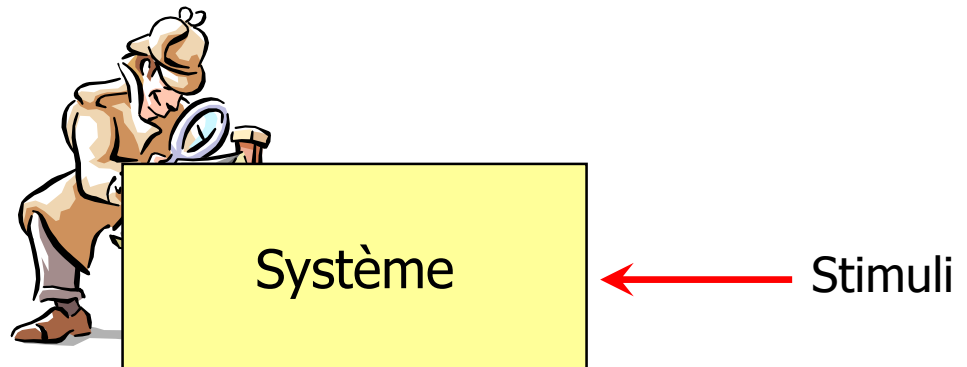

- ❑ Trace-based approach
  - ❑ Explicit description of interactions in a system after a given stimuli
  - ❑ Empirical approach
- ❑ Model-based approach
  - ❑ Use of a mathematical language to model system dynamics
  - ❑ Formal approach

# Traces

---

- ❑ Principles
  - ❑ Trace all the interactions between structural elements during the execution of a scenario
  - ❑ Traces are complete for a given scenario
  - ❑ Union of all possible scenarios provides a complete behavioral model (not feasible)
- ❑ Popular approach
  - ❑ UML
  - ❑ Architecture

# Scenario

---

- ❑ A scenario represents a system usage
  - ❑ A scenario is triggered by an event in a context
  - ❑ It triggers a sequence of interactions between components
  - ❑ It exemplifies an internal behavior of the system
  
- ❑ It is not a use case

# Scenario - representation

---

## **Scenario : nominal purchase**

### **Description**

The scenario begins when a client pushes « start » button.

Then , the client selects a product et introduces his card.  
The corresponding account is debited and the product is provided.

End of the scenario.

### **Actors**

1. The client

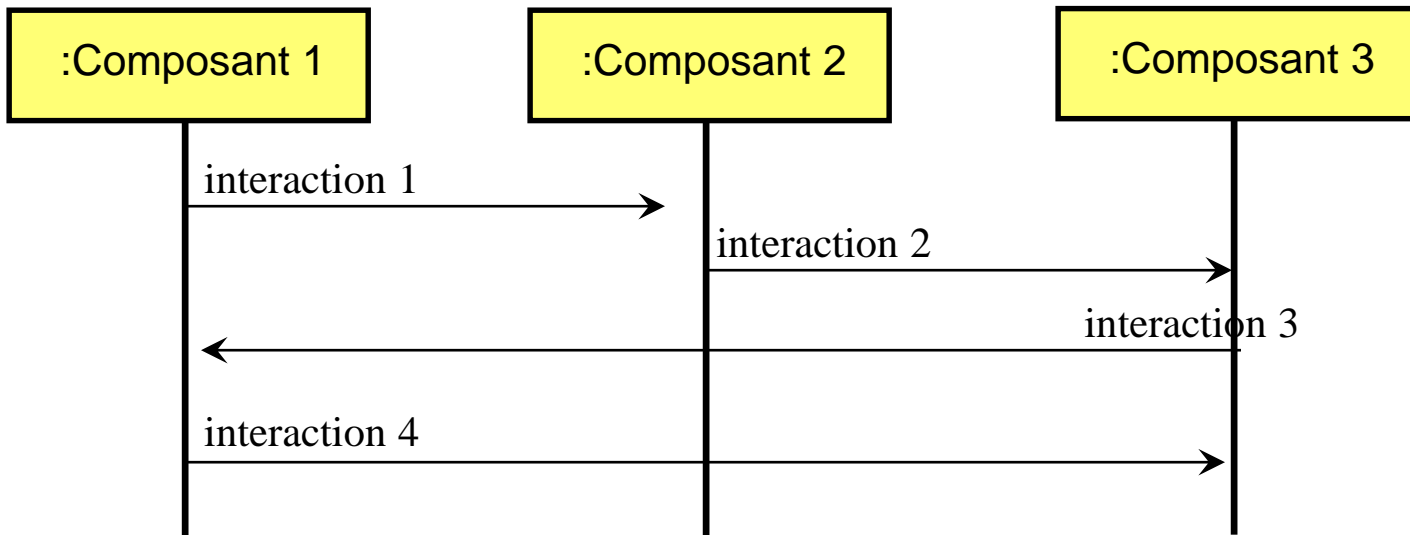

### **Exceptions**

- The client can leave before entering his card
- Etc.

# Scenario – advanced representation

---

## ❑ Sequence diagrams

# Side notes

---

- ❑ These diagrams only contain elements implied in a scenario
- ❑ Invoked interfaces are on the arrows
  - ❑ more or less detailed
  - ❑ depends on the design advancement
- ❑ Concurrent activities are hard to express
- ❑ A constraint language can be used to get more precise
  - ❑ OCL (Object Constraint Language) of UML is an example

# Interests of traces

---

## ❑ Advantages

- ❑ express (partially) a system dynamics
- ❑ provide a good support to design
- ❑ Pragmatic and easy to use
- ❑ Allow a few validations to be performed
  - ❑ Paths complexity, bottlenecks, ...

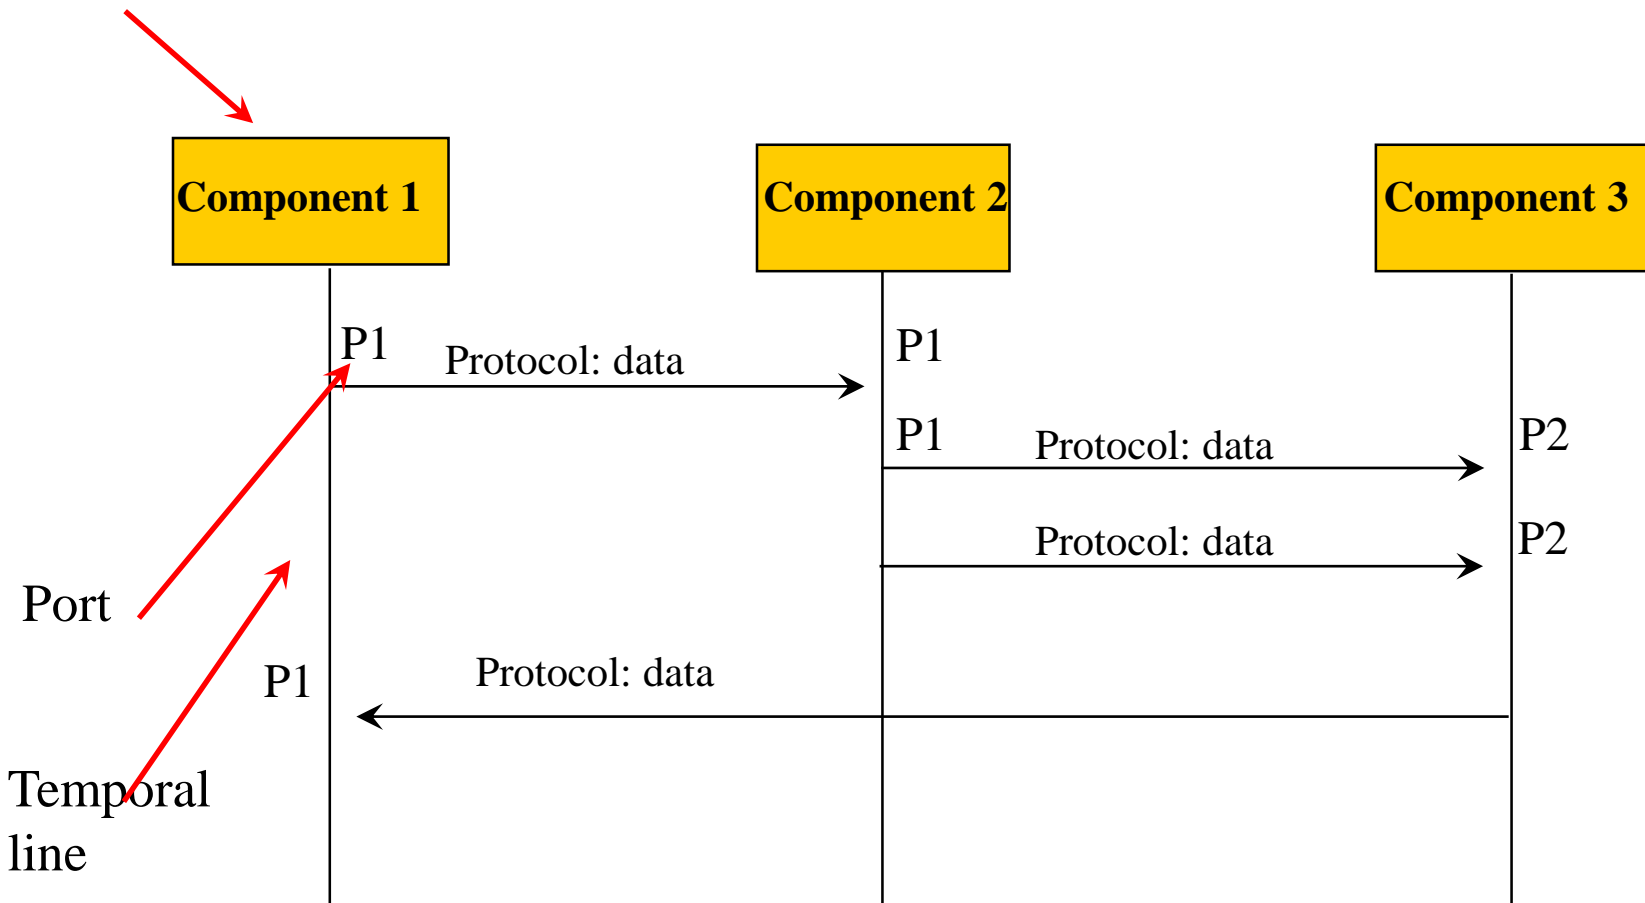

## ❑ Problems

- ❑ cannot cover the whole dynamics
- ❑ Very difficult to identify the good set of traces
- ❑ Analysis/validation remains limited

# Formalism

---

Component

# Example

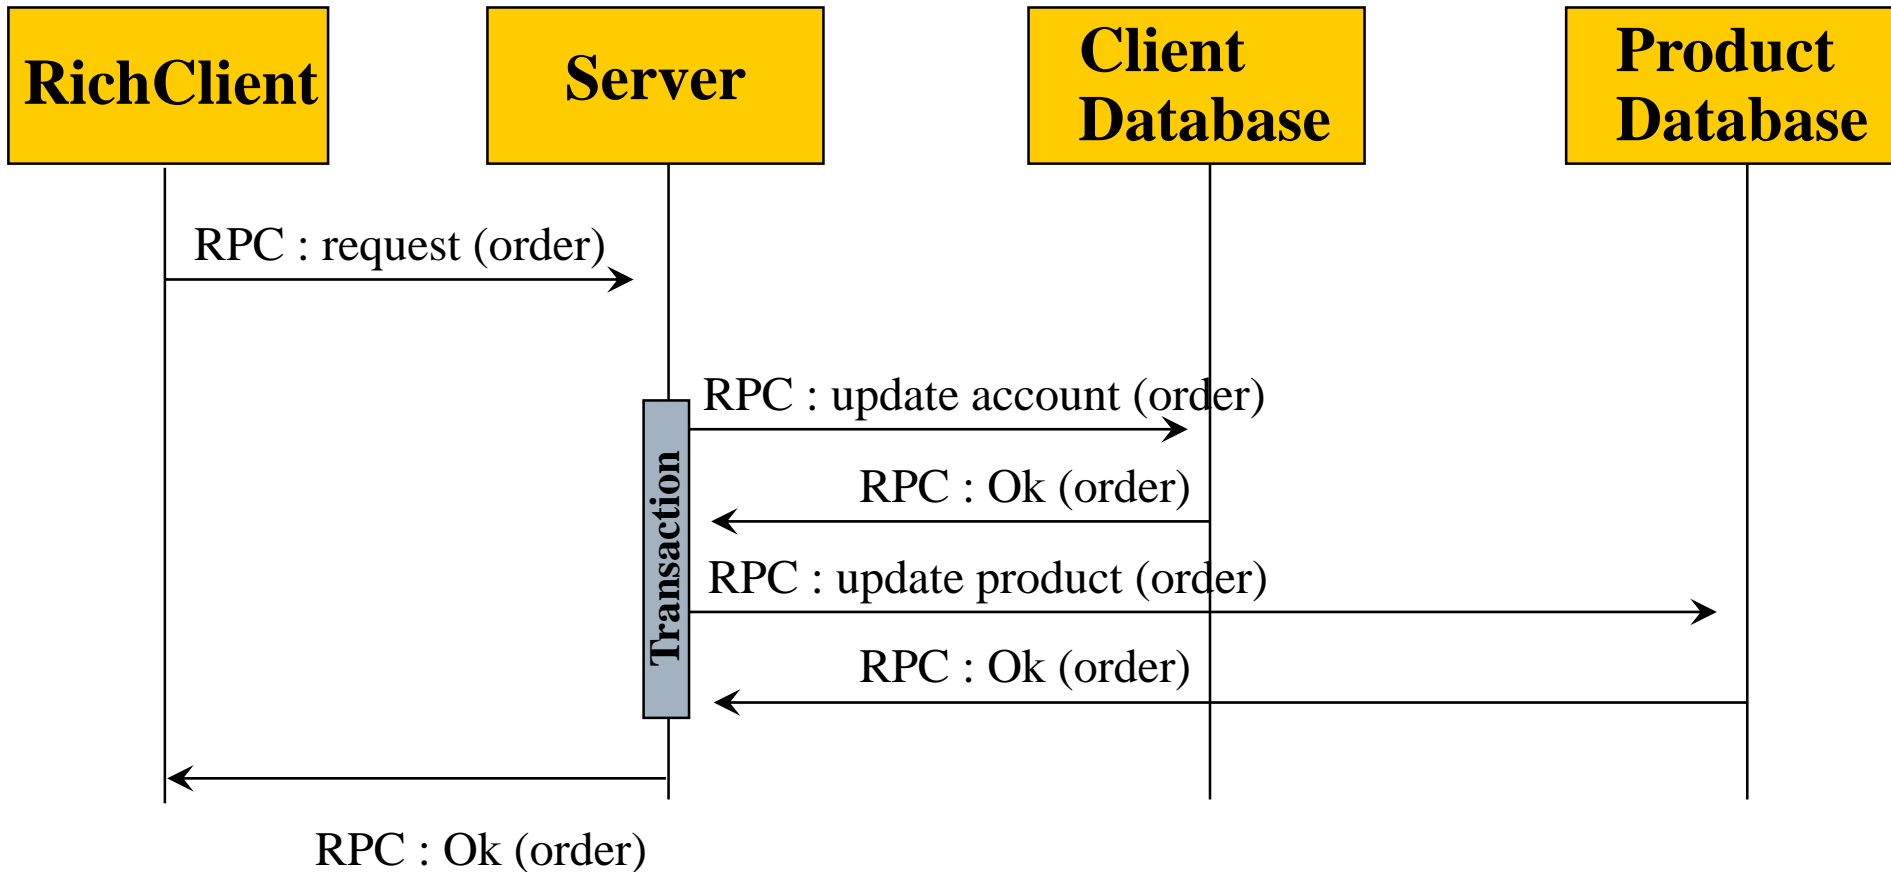

---

## ❑ Scenario

- ❑ Description: Shows what happens when a borne sends a command to the main server
- ❑ Triggering event: a payment is done. Such an event may happen anytime
- ❑ Context: nominal behavior. The main server is not overloaded and there is no concern with the client credit card.

# Example

---

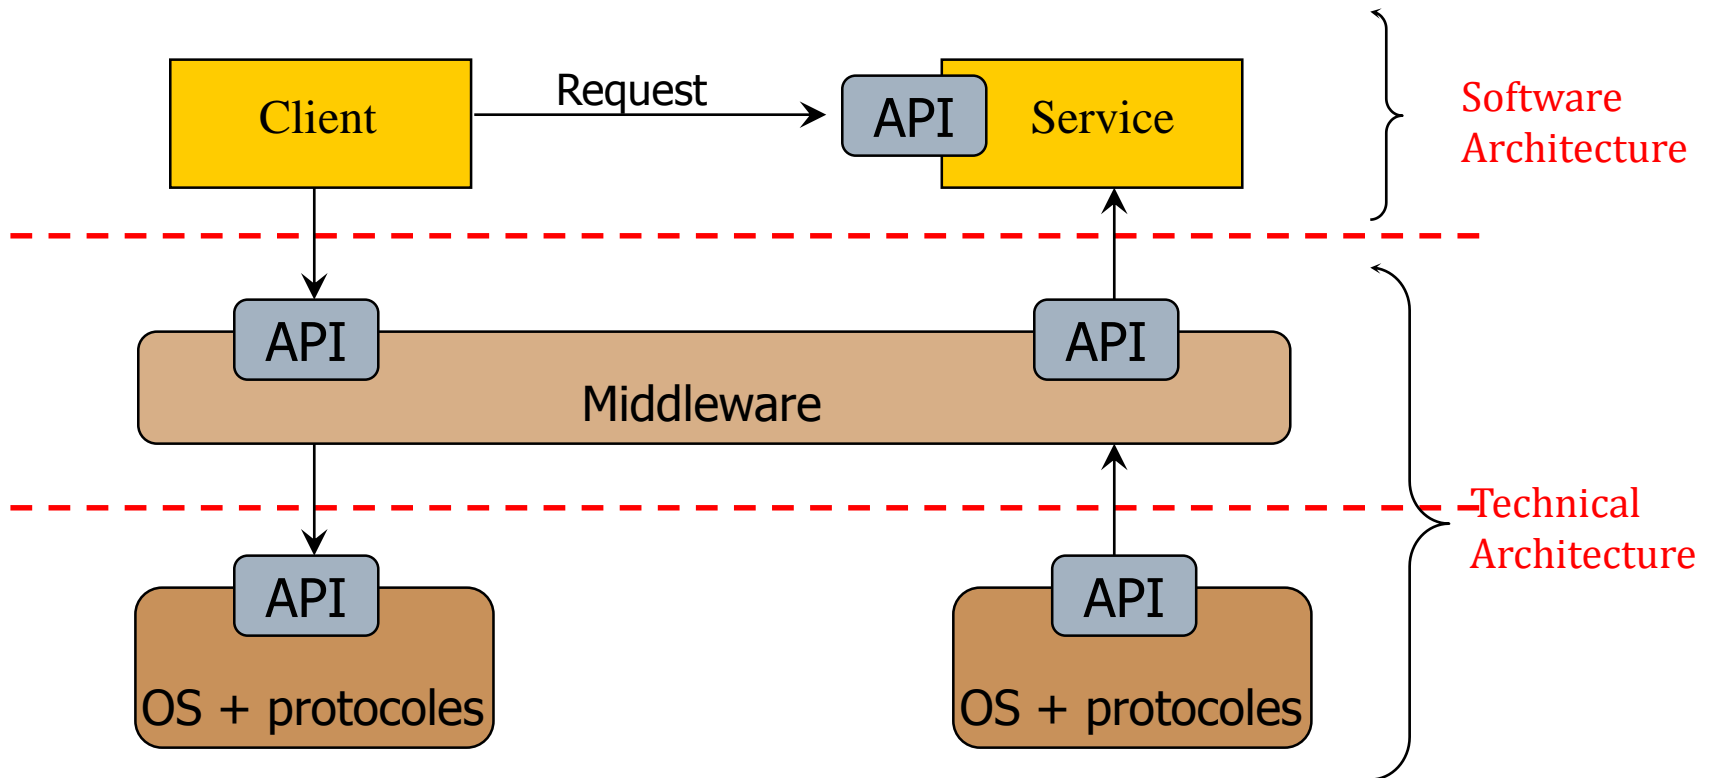

# Outline

---

- ❑ Architectural views
- ❑ Logical views
- ❑ Dynamic views
- ❑ Allocation views
- ❑ Conclusion

# Allocation view (reminder)

# Allocation view

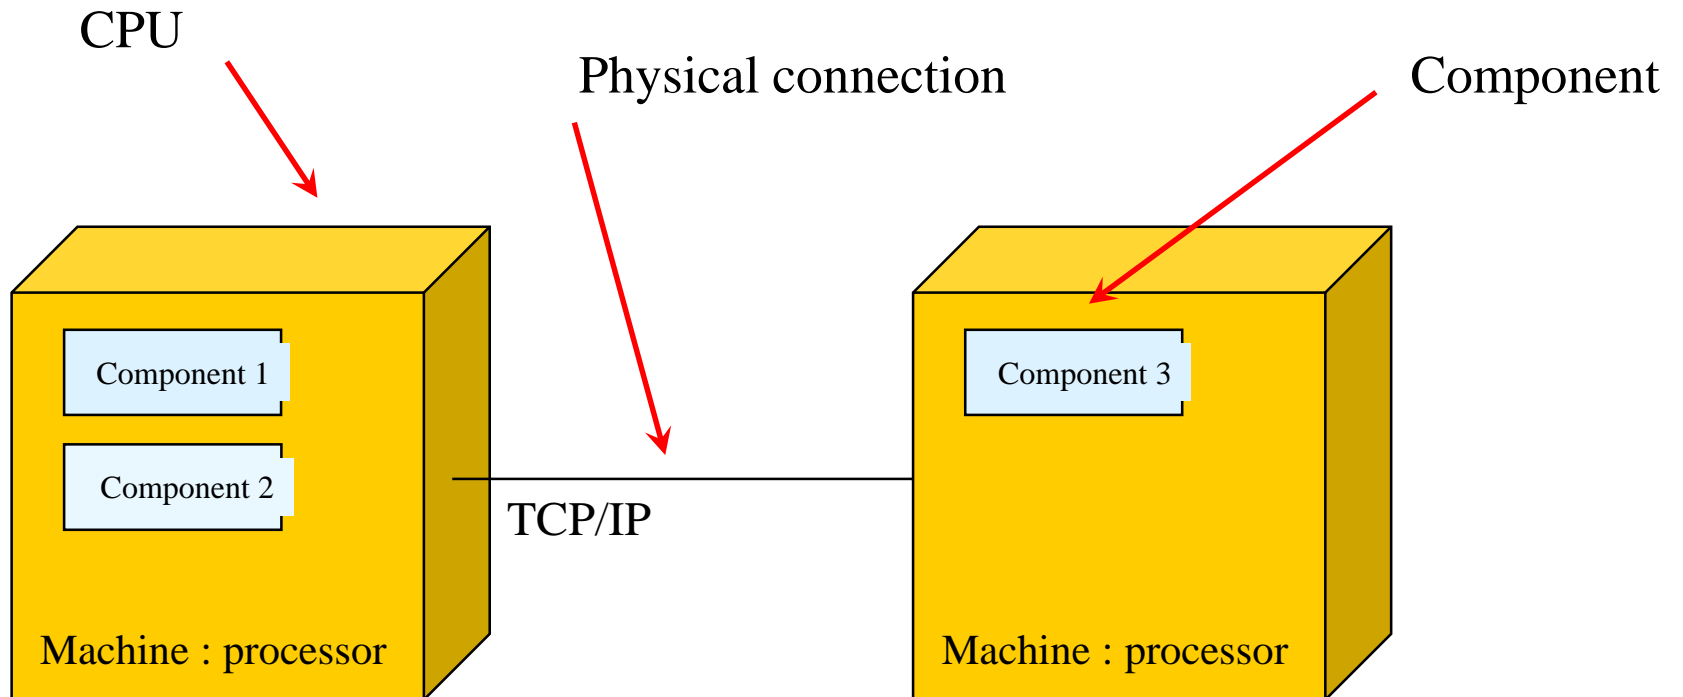

---

- ❑ Represent the mapping of the structural elements onto
  - ❑ Physical resources
  - ❑ Middleware

# Formalism

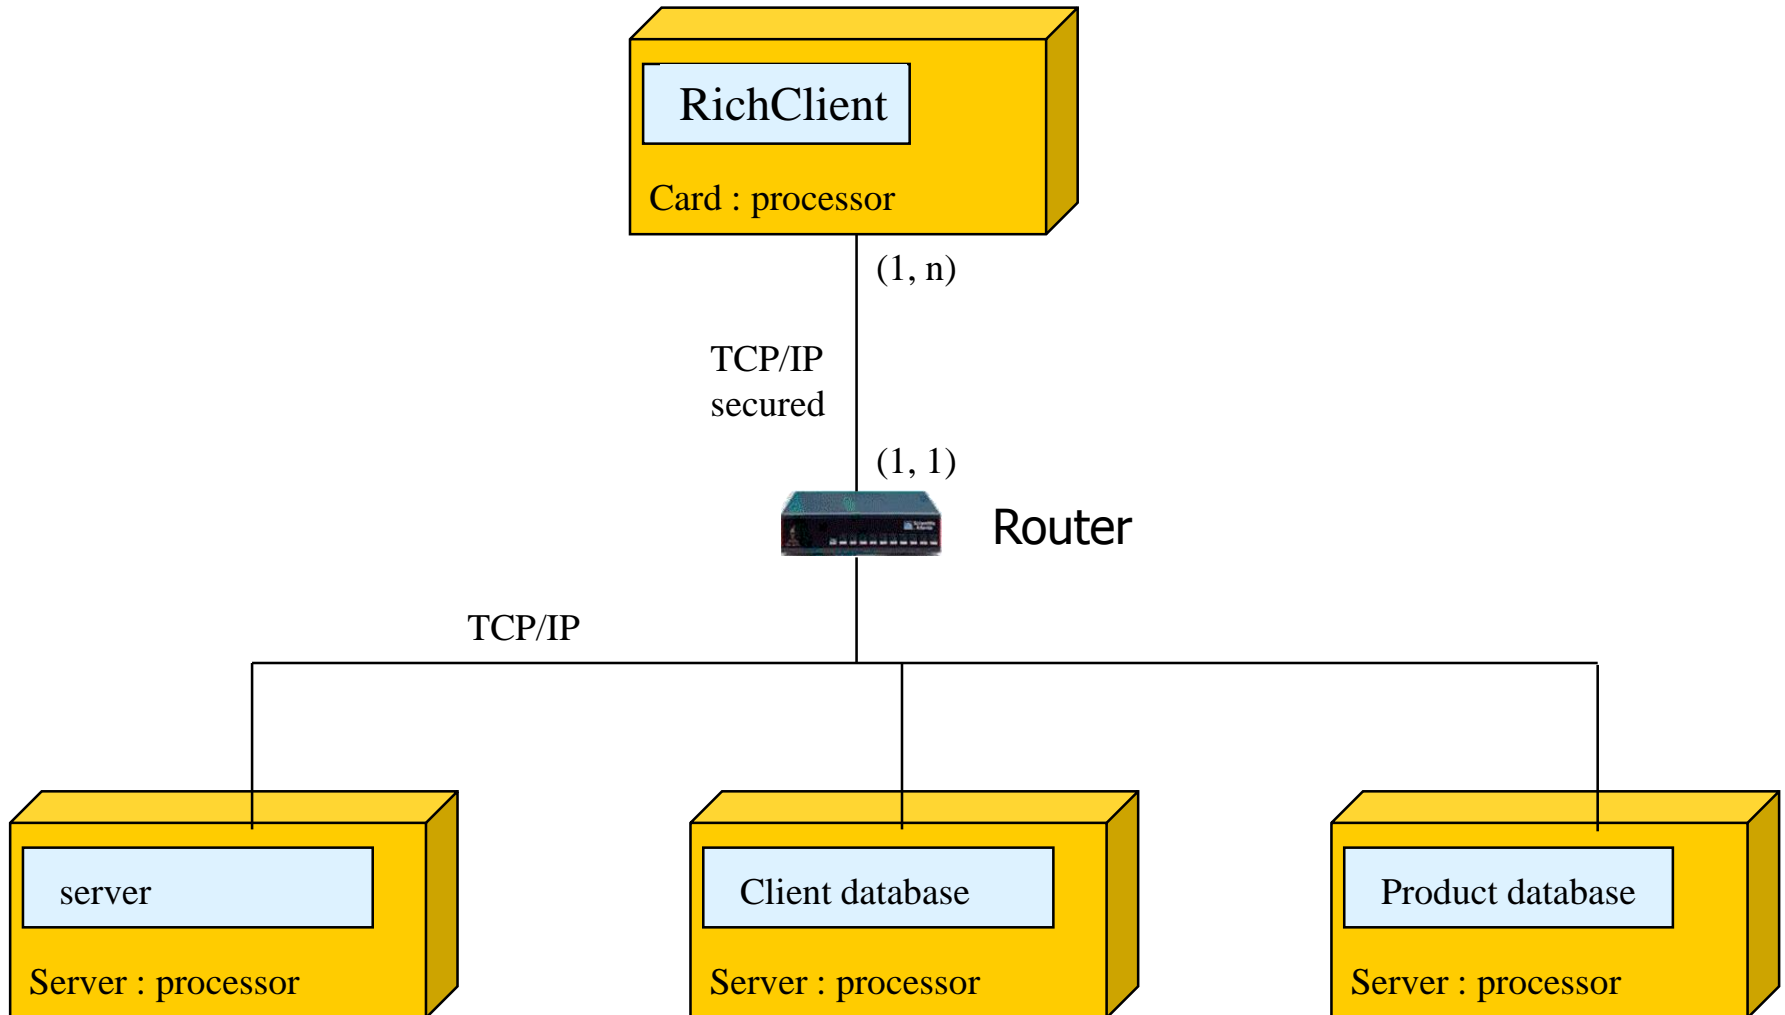

---

# Example

---

# Outline

---

- ❑ Architectural views
- ❑ Logical views
- ❑ Dynamic views
- ❑ Allocation views
- ❑ Conclusion

# Major points

---

- ❑ An abstract specification
  - ❑ Architecture is a model
- ❑ Conceptual vs. technical detail
  - ❑ Different levels of specification
- ❑ Architectural views
